6 **Sensing Beauty**

7 Somewhere along our evolutionary path, the
8 human lineage developed an obsession with
9 beauty in sounds and objects. The clue to under-
10 stand the biology behind this phenomenon lies in
11 a dictionary definition of beauty: “A quality that
12 gives pleasure to the mind.” Humans are
13 equipped with several types of senses, but only
14 the two based on eyes and ears transmit signals
15 associated with aesthetics. Thus, the pertinent
16 question when it comes to understanding the
17 biology of aesthetics is “Why are certain visual
18 and auditory stimuli processed in a way that gives
19 us pleasure?” The brain receives a continuous
20 flow of sensory information. Most signals are
21 neutral, some may be repulsive, but
22 a considerable variety of signals have the poten-
23 tial of eliciting some sort of pleasure. The term
24 aesthetics, however, is generally limited to stim-
25 ulti derived from sounds or objects produced with
26 the aim of eliciting a positive experience. In other
27 words, aesthetics is about man-made creations
28 that offer pleasure based on our auditory and
29 visual senses. Evolution did not give us eyes
30 and ears for the purpose of idle pleasures. They
31 are part of a survival kit. Looking at a painting or

listening to music is unlikely to help you survive, 32
yet people spend a fair amount of time doing just 33
that. This entry tries to explain why. 34

The Many Components of Art

35

A concern for aesthetics appears to be a universal 36
feature among human cultures, strongly 37
suggesting that there are innate mechanisms 38
behind. The evolutionary perspective may, there- 39
fore, help explain why we care about beauty, and, 40
possibly, suggest what aspects of music and art 41
that tingle our brain in a way that causes 42
satisfaction. 43

First, one needs to dissect what art is about, 44
that is, to distinguish between aesthetic elements 45
and other aspects. Aesthetics serves several cul- 46
tural functions, such as communication with God, 47
and influencing people’s political ideas. More- 48
over, art has obvious economic aspects, not just 49
in the value of pieces of art, but also in the use of 50
aesthetics to sell products. Another highly rele- 51
vant feature is the potential that art has in offering 52
status to those with relevant skills – a point that is 53
particularly relevant when it comes to attracting 54
a mate. 55

Another way of dissecting art is to distinguish 56
between pure aesthetic elements and experiences 57
based on the associative content; for example, 58
a love song may stimulate some of the positive 59
feelings involved in love, and a painting of a baby 60
may warm the heart of adults. 61

62 This entry focuses on the elements that add
63 what may be referred to as *aesthetic value*. It is
64 assumed that these elements operate independent
65 of cultural implications and associations
66 involved. This statement is backed by the obser-
67 vation that people tend to agree upon what is
68 good, or not so good, in art derived from different
69 cultures. It implies that there are vaguely defin-
70 able aesthetic rules, employed by the artists,
71 which add a particular artistic quality. These
72 rules, or elements, are what we look for when
73 distinguishing between a bowl with solely func-
74 tional value and a bowl with added aesthetic
75 value; or cherished music compared to just
76 noise. While many aspects of art depend on par-
77 ticular individual or cultural parameters, the
78 underlying aesthetic elements appear to rely on
79 innate features of the human mind. These more
80 intuitive elements are not necessarily the most
81 important, but they are the focus of this entry.
82 Other aspects of art, not the least its function in
83 mate choice, have obvious biological implica-
84 tions, but they are considered less relevant when
85 discussing aesthetics.

86 Brain Rewards

87 The intuitive aesthetic elements is a question of
88 what sort of visual or auditory signals that are
89 likely to be processed by the brain in a way that
90 gives the observer a positive feeling. In order to
91 appreciate this perspective, it is important to have
92 a basal understanding of why the brain offers
93 positive and negative experiences. As a general
94 rule, feelings serve one of two functions: they
95 either encourage or discourage particular types
96 of behavior. Food taste good, so you eat. It hurts
97 to burn your finger, so you avoid fire. In other
98 words, feelings tend to come in two flavors: pos-
99 itive or negative. This is, of course, a simplified
100 version of reality. In many instances, the value is
101 less obvious and quite often it depends on the
102 situation. Some people enjoy the thrill of
103 a dangerous task, such as climbing a mountain,
104 while others consider it a totally unpleasant
105 affair. Still this bipolar view of brain instigation
106 is useful for the present purpose. Thus, I shall use

107 the terms brain rewards and brain punishments to
108 signify sensations experienced as respectively
109 positive and negative. Some further comments
110 are called for. Employing your brain or body to
111 do what they are designed for is generally posi-
112 tive, in the sense that it is good for your genes,
113 and therefore, connected with rewards. This
114 implies that even sadness may “feel good”
115 because it is a reaction that under certain circum-
116 stances serves you well. Signs of sadness may, for
117 example, elicit help from others. Several Holly-
118 wood productions testify to the potential value of
119 sorrow – people flock to movies that make them
120 cry. Another important point to note is that
121 reward-type mechanisms for directing behavior
122 are not necessarily adaptive in the situation we
123 live in at present. The reward of an orgasm feels
124 good regardless of contraceptives. For the genes,
125 unproductive sex can be seen as a waste of time,
126 but the genes did not foresee the invention of
127 contraceptives. Likewise, adding aesthetic value
128 to an object or a work of art does not necessarily
129 give any evolutionary advantage. The essential
130 feature of aesthetics is to evoke feelings per-
131 ceived as positive. The feelings do not need to
132 be cheerful, neither is any engagement in art
133 necessarily adaptive. The brain offers “rewards”
134 because directing your attention to particular
135 types of sensory input was adaptive at some
136 point in our evolutionary history.

Visual Aesthetics

137
138 Our ancestors began to walk upright some
139 3–4 million years ago, thereby freeing their
140 hands for more advanced manipulation of tools.
141 Tools can be of obvious importance for survival,
142 the surprising part is that at some point people
143 started to add beauty to the objects. Today we
144 have moved one step further: We create objects
145 of art with no apparent practical value. The first
146 obvious signs of this propensity, in the form of
147 cave paintings and the production of figurines,
148 date back some 40,000 years. However, 149
150 archaeologists have discovered signs of similar
151 behavior at least 100,000 years ago, in the form
of presumed shell necklaces and the use of

Au1 152 pigments. Most likely artistic behavior goes back
153 much further, but the evidence is long lasting. In
154 fact, even chimpanzees appear to take delight in
155 producing art – which is not surprising, as the
156 aesthetic elements to be discussed below presu-
157 mably have a long evolutionary history.

158 **Elements of Visual Aesthetics**

159 **Balance and Symmetry**

160 One of the few rules of aesthetics that has won
161 a certain acceptance is the principle stating that
162 the main motif in a picture should divide the
163 canvas in a ratio of approximately 3:5. What the
164 principle suggests is that placing an object in
165 the middle is boring, while placing it too far to
166 one side produces an unbalanced appearance.
167 The ratio of 3:5 is supposedly the optimal com-
168 promise between these two undesirables. The
169 disagreeable effect of the unbalanced picture is
170 possibly connected with our fear of falling.
171 Falling is not a common problem for an animal
172 stationed on the ground, but our ancestors did at
173 one point live in trees. Furthermore, even ground-
174 dwelling animals would be conscious of the pos-
175 sibility that an unbalanced rock may roll.
176 A dominant object on one side of a picture gives
177 the unpleasant impression that this side is tilting
178 unless a balance is added on the opposite side. On
179 the other hand, we tend to cherish a bit of excite-
180 ment. Thus, the choice is much a question of what
181 sort of subconscious feelings the artist aims for:
182 thrill or calmness. Both offer possible brain
183 rewards.

184 In some cases, an exact balance may add par-
185 ticular value. Symmetry is appreciated. Perfect
186 symmetry in a person's anatomy, or in a prey
187 animal, is a sign of gene quality, which is to be
188 desired. The positive value of symmetry in
189 connection with aesthetics is most obvious in
190 architecture. Many buildings considered to be
191 great works of art have symmetrical features.

192 **Color**

193 Many plants offer nourishment to animals in
194 exchange for helping their seeds. Tomatoes, for
195 example, are meant to be eaten – the perfect start

196 for the seeds of this plant is to end up in feces. In
197 order to signal that the fruit is ready to be eaten,
198 a conspicuous color is usually added. Animals
199 have evolved the ability to respond accordingly.
200 They have a visual system enabling them to spot
201 ripe fruit. Fruits and berries are important for
202 human sustenance. To induce us to find them,
203 we presumably developed appropriate brain
204 rewards, that is, an appreciation of colorful
205 objects that contrast with the surroundings.
206 I believe these rewards constitute an element in
207 the biology of aesthetics. In line with this notion,
208 we do indeed appear to prefer warm colors, such
209 as red or yellow – particularly as opposed to
210 brown. Ripe fruit is typically red or yellow,
211 while feces, a substance to be avoided, are
212 brown. Colors that are light and fresh tend to be
213 considered pleasant while darker, and muddier,
214 colors, particularly brownish or grayish, tend to
215 be depressing. Humans thrive in daylight. How-
216 ever, as pointed out above, even sadness can be
217 conceived as a positive sensation. Thus, the artist
218 may very well create a great painting using dark
219 brown rather than brilliant red.

220 **Curiosity and Attention**

221 Some animals are specialists. Cows, for example,
222 concentrate their attention on a limited range of
223 visual impressions, such as the quality of grass.
224 Humans are quite the opposite. We are specialists
225 in nonspecializing. We are stimulus-hungry and
226 have an inclination to gather all sorts of informa-
227 tion from our surroundings. Survival often
228 depends on careful observation, such as finding
229 the way, gathering food, and recognizing faces.
230 Exploratory behavior is, therefore, connected
231 with brain rewards. The term “boring” is used in
232 aesthetics when there is not sufficient variation or
233 novelty in a work of art. The object lacks suffi-
234 cient detail to attract attention. On the other hand,
235 complexity stimulates our curiosity and is, there-
236 fore, pleasing. A too complex visual input may,
237 however, prove adverse. The mind needs to find
238 clues that can help it organize the details. Thus,
239 there should be a unity in the diversity. In the
240 aesthetic tradition of the Chinese, there is
241 a concept called “The rule of five,” referring to
242 the limitations of the human attention span:

<p>243 The mind can without too much effort grasp five 244 elements at a time. If too many unconnected 245 elements are added, the impact may be stressful. 246 As a rule of thumb, the complexity should not 247 move beyond the attention potential of the human 248 brain.</p> <p>249 Depth and Movement</p> <p>250 Binocular vision is typical for primates. This 251 feature is probably connected with the visual 252 requirements of living in trees. Moving from 253 branch to branch demands an accurate ability to 254 measure distances. In order to take full advantage 255 of the various potentials of the brain, we need 256 practice. Children are encouraged to practice by 257 participating in play activities. The purpose of 258 play is to learn tasks that the brain has 259 a rudimentary potential for performing, but 260 which yet require further training. The brain 261 rewards us for developing our potentials. Our 262 ability to measure depth and calculate move- 263 ments requires practice. We may, therefore, be 264 rewarded for processing visual input relevant to 265 this task. A typical criticism of amateur paintings 266 is that they appear flat. We appreciate a painter 267 who manages to create the perception of depth. It 268 is possible to lure the brain into perceiving 269 motion by adding dots of different colors, but 270 the same light intensity. Furthermore, a picture 271 may contain lines that the eyes are induced to 272 follow, and thus offer the viewer a sense of 273 movement.</p> <p>274 Functionality</p> <p>275 The idea that the functional is also visually attrac- 276 tive was particularly influential on architecture in 277 the 1930s. A central doctrine then was that form 278 should follow function. A related idea is that art 279 should try to perfect nature. Beauty has been 280 described as a “comprehensible representation 281 of the perfect.” There are obvious reasons why 282 looking for functionality and perfection should be 283 connected with a reward. Consuming rotten food 284 may be dangerous, whereas eating the best spec- 285 imens keeps you healthy. Moreover, it is impor- 286 tant to recognize the functional qualities of tools. 287 Receiving a pleasant sensation when viewing the 288 right objects helps the individual to distinguish</p>	<p>good from bad, and stimulates us to try to obtain the better items.</p> <p>Art as Hedonism</p> <p>The above list of elements is not necessarily exhaustive. The focus has been on presenting a way of understanding aesthetics. The list includes what I believe to be the more important factors. Our visual system, including the accom- panying reward mechanisms, was developed for viewing nature, not artificial objects. The attri- butes of our vision, as well as the characteristics of nature, may guide us in an attempt to find and utilize aesthetic elements. Obviously, there are numerous ways of eliciting rewards. Thus, the theory presented here does not restrict the artist to narrow rules. The present understanding of aesthetics is related to a dominant philosophy of art sometimes referred to as the <i>hedonist school</i>. Its central idea is that aesthetics is about creating images that induce pleasure. The biological model adds substance to this theory. It agrees with the central notion, but by using the word “pleasure” in a broader sense, the model helps resolve a paradox of the hedonist school: Why so many of the great works of art reflect sadness and tragedy? As explained above, the feeling of sad- ness is not necessarily negative.</p> <p>Auditory Aesthetics</p> <p>Music can arouse a surprisingly intense emo- tional response. The biological approach to understanding the human mind may offer an explanation. Again, the answer depends on insight into why certain sensory stimuli are processed in a way that engaged reward-type nervous circuits. Although musical appreciation is clearly influenced by nurture, several argu- ments favor the notion that the appreciation of music is an innate trait. One line of evidence for a genetic influence is the universality of musical appreciation. Most cultures make use of music, if not with advanced instruments, in the form of song and rhythm. Playable flutes that are almost</p>	<p>289 290</p> <p>291</p> <p>292 293 294 295 296 297 298 299 300 301 302 303 304 305 306 307 308 309 310 311 312 313 314 315</p> <p>316</p> <p>317 318 319 320 321 322 323 324 325 326 327 328 329 330</p>
--	--	--

331 9,000 years old have been found in China, and
 332 a piece of bone discovered at a Neanderthal site
 333 had holes drilled into the hollow part, suggesting
 334 that even they made flutes. The observation that
 335 musical appreciation apparently arises spontane-
 336 ously in children offers further evidence and so
 337 does the powerful effect music has on the human
 338 mind. The Neanderthal lineage diverged from the
 339 lineage leading to present-day humans more than
 340 half a million years ago. Thus, the ability to
 341 appreciate music may have been present in hom-
 342 inids for a long time.

[Au2]

343 **The Language Connection**

344 Accepting that our passion for music is based on
 345 an innate tendency, the question is: Why is the
 346 human brain designed to connect certain forms of
 347 auditory signals with pleasurable sensations? In
 348 other words, what sort of evolutionary forces
 349 carved this tendency into the human mind? Oral
 350 language is the most obvious advantage associ-
 351 ated with complex sounds. A possible evolution-
 352 ary connection between language and music has
 353 been discussed by several authors, starting with
 354 Darwin in his “Descent of Man.” I shall expand
 355 on this connection, in an attempt to develop
 356 a coherent theory for the evolution of musical
 357 appreciation. The language connection is the piv-
 358 otal element, but other forces are presumably also
 359 involved. The way human infants learn language
 360 is different from the way birds learn to vocalize.
 361 The sound-producing capacity of most birds
 362 tends to be fixed. Some are able to learn by
 363 imitation and to elaborate on themes, thus creat-
 364 ing both dialects and individual signatures, but
 365 their song is mainly hard-wired. Humans are born
 366 with an innate capacity for language, but this is
 367 only a template; extensive practice is required in
 368 order to learn to produce and decipher language.
 369 Physical play is necessary for infants to develop
 370 the nerve circuitry required for muscular coordi-
 371 nation. Focusing the mind on the production and
 372 interpretation of sounds is presumably adaptive
 373 behavior because it helps develop the nerve cir-
 374 cuitry required for language. As such, this activ-
 375 ity should be coupled with positive sensations.

376 According to this hypothesis, our appreciation for
 377 music was designed by evolution primarily in
 378 order to improve brain structures involved in
 379 language. It might be argued that the hypothesis
 380 would predict that a preoccupation with music, as
 381 with other play behavior, should be associated
 382 with children. In response to that, it may be
 383 noted that even when the main circuitry has
 384 been established, the mind presumably continues
 385 to pay attention to sounds for two reasons: Firstly,
 386 as adults we may still need to exercise our sound-
 387 producing and interpreting capacity. Secondly,
 388 we are stimulated not just to improve our senses,
 389 but also to use them in exploratory behavior. Exploratory behavior, that is, taking an interest
 390 in our surroundings, may decrease upon ageing,
 391 but does not disappear. The concept of agreeable
 392 sensations designed for the purpose of improving
 393 the capacity for oral communication, as well as
 394 for stimulating an interest in sounds, can explain
 395 it; but then why are not all sounds equally pleas-
 396 ing? A further analysis is required to understand
 397 why we distinguish between noise and music –
 398 that is, we need to describe the features that cause
 399 auditory signals to be pleasing. 400

401 **Elements of Auditory Aesthetics**

402 **Complexity and Coherence**

403 As in the case of visual art, a certain complexity
 404 of sounds presumably has a positive effect on the
 405 listener. A single, pure tone is not that interesting
 406 to explore. A measure of intricacy is required to
 407 excite human curiosity. Sounds that are too com-
 408 plex, however, tend to be overwhelming. We
 409 presumably prefer some sort of coherence, that
 410 is, a principle that connects the various sounds
 411 and make them comprehensible.

412 **Purity and Harmony**

413 The tendency to prefer pure sounds is a central
 414 element in the enjoyment of music, and a possible
 415 consequence of the language connection. The
 416 preference for purity and consonance appears to
 417 be innate. One reason why these qualities are
 418 favored may be because they enhance oral com-
 419 munication. The capacity to produce pure sounds

420 is most advanced in animals in which auditory
 421 signals are the prominent form of communica-
 422 tion, such as songbirds and whales. A pure tone
 423 presumably carries further, and although lan-
 424 guage typically includes a mixture of relatively
 425 pure (vowels) and dissonant (consonants) sounds,
 426 harmony is expected to reduce ambiguity. The
 427 brain centers involved in the production and
 428 processing of sounds are probably predisposed
 429 to prefer sounds with suitable qualities. Some
 430 languages are referred to as tone languages; that
 431 is, the meaning of a particular sound depends on
 432 the pitch. Speakers of these languages appear to
 433 be more able to recognize variations in pitch
 434 compared to speakers of non-tonal languages. It
 435 is conceivable that the first human languages
 436 were more like song, or at least depended on
 437 pitch, which would lead to an augmented interest
 438 in this aspect of sounds.

439 **Temporal Patterning and the Human Touch**

440 A main feature of human language, as opposed to
 441 oral communication in apes, is the importance of
 442 the temporal patterning of sounds. Single sounds
 443 are in most cases not sufficient to convey mean-
 444 ing, whereas when put together in a sequence
 445 they form words and sentences. Temporal pat-
 446 terning is equally important in music – if the
 447 tones are not in some way tied together sequen-
 448 tially, people are unlikely to show appreciation.
 449 The temporal patterning is related to what the
 450 musical literature refers to as melody. It is con-
 451 ceivable that music requires similarities to lan-
 452 guage, such as complexity and melody, in order
 453 to be valued, because only then does it utilize the
 454 brain resources involved in processing spoken
 455 words. Another element in the appreciation of
 456 sounds, as in visual arts, is the communicative
 457 aspect. Humans seek to gain knowledge about
 458 other individuals as part of our social nature.
 459 When a person creates sounds, we tend to search
 460 for a message, or at least we expect that some-
 461 thing about that person’s emotional life can be
 462 inferred. A voice satisfies this criterion, the same
 463 goes for an instrument in the hands of a skilled
 464 musician, while it is difficult to program
 465 a computer to display emotion. In other words,
 466 the complexity should have a human flavor. It is

interesting to note that people tend to agree, at
 least to some extent, on what emotions a given
 sequence of music reflects.

Safe and Relaxing Sounds

The appreciation of music depends on a variety of
 qualities of sounds, the language connection does
 not necessarily explain them all. Music can have
 a relaxing effect not only on humans, but on
 animals as well. One possible explanation for
 the relaxing effect is that music is continuous
 and rhythmical. In a natural environment, danger
 tends to be accompanied by sudden, unexpected
 sounds. A background of constant noise suggests
 peaceful conditions; discontinuous sounds
 demand more attention. Even soft discontinuous
 sounds that we consciously realize do not signal
 danger can be disturbing, for example, the drip-
 ping of a leaky tap. A continuous sound, particu-
 larly one that is judged to be safe, relaxes the
 brain. As to the soothing effect on humans, it
 may also be pointed out that music presumably
 is intuitively understood to be man-made, and as
 such normally not related to dangerous situations.

Rhythm

One of the most characteristic features of music is
 rhythm. In tribal music, rhythm instruments are
 often the main element, but even elaborate music
 seems to require rhythm in order to be appreci-
 ated. The rare cases of experimental music with-
 out a beat have, as expected, not enjoyed
 commercial success. Rhythm is probably appre-
 ciated because it helps us organize the sound, and
 because it is a comforting feature. The comfort
 can be related to the absence of danger associated
 with rhythmic sounds, but also to a resemblance
 to the pulse of the mother’s heart imprinted pre-
 natally. Newborns appreciate sound in the form
 of voices, vocal music, or heartbeats.

The Chill

The above suggestions may explain a general
 appreciation for music, yet the emotional
 response is sometimes more overwhelming than
 what would be anticipated. Particular passages

510 can generate an intense pleasurable experience
511 described as a chill or a thrill. It is not an expected
512 evolutionary strategy to encourage a certain type
513 of behavior in excess of what is adaptive.
514 A person who is preoccupied with song or
515 music pays less attention to other tasks or to
516 possible dangers. For example, if you are
517 engrossed in singing you are unlikely to detect
518 an approaching predator. Thus the rewards asso-
519 ciated with sounds should not divert our attention
520 to a greater extent than what the contribution to
521 survival suggests. The chill appears to be exces-
522 sive encouragement. Certain qualities of music
523 that tend to produce chills point toward a possible
524 explanation. Research suggests that chills are
525 evoked more often by sad music than by happy
526 music, by familiar music rather than an unknown
527 piece, and intense passages, such as crescendos,
528 are particularly chilling. Chills are more com-
529 monly experienced by women than by men. It is
530 conceivable that chills hook directly onto the
531 brain's primitive emotional circuits; more specifi-
532 cally, that music has some sort of relationship
533 with the call of an infant crying for its mother.
534 Separation calls are expected to evoke powerful
535 feelings in parents – especially in mothers.
536 Human separation calls have properties related
537 to chill-producing sounds: the cry of a baby is at
538 once intense, familiar, and sad. Long before the
539 development of language, the genes had presum-
540 ably designed the brain to offer ample rewards to
541 ensure attentiveness to the call of infants. It is
542 possible that a chill is an accidental sensation
543 evoked when music happens to approach the
544 sounds we are programmed to react to as care-
545 givers. However, it is also conceivable that a chill
546 can be explained by the way evolution tends to
547 utilize structures already present for novel pur-
548 poses, as exemplified by the way legs evolved
549 from the fins of fish. The need for positive sensa-
550 tions to encourage the processing and production
551 of sounds, which I suggest appeared as
552 a consequence of the introduction of language,
553 may have triggered evolution to recruit the emo-
554 tional pathways associated with parents' atten-
555 tion to the cries of their babies.

Sexual Selection

556

557 An artist may feel that reducing aesthetics to an
558 innate trait does not do either music or art justice.
559 It is important to stress that the biological
560 approach reflects only one of several possible
561 perspectives relevant to the understanding of art.
562 Moreover, in present society art has gained a "life
563 of its own," partly independent of our innate
564 preferences for particular qualities. The
565 suggested elements, and concomitant rewards,
566 promote a preoccupation with certain types of
567 sounds and visual stimuli. Obviously, the partic-
568 ular taste of an individual is governed by personal
569 and cultural traits. Thus, the observation that the
570 same music or painting may produce pleasure in
571 one person and discomfort in another does not
572 contradict the suggested aesthetic elements. It
573 was pointed out already that art serves several
574 cultural functions, such as communication with
575 both humans and spirits. It is possible that these
576 functions contributed to the evolution of our
577 innate preoccupation with art. Communication
578 involves obtaining attention. However, both
579 attention and communication may be achieved
580 without adding beauty. A traffic sign is perfectly
581 designed for attracting attention, yet few would
582 treasure it as a work of art. Paintings, on the
583 contrary, are sometimes very subtle and quiet.
584 Furthermore, much of the art produced, such as
585 that of children or amateurs, is apparently made
586 solely for the satisfaction of the creator, and not
587 for communicating with others. The greatest
588 works of art are probably produced when aes-
589 thetic elements are used to enhance the commu-
590 nicative content. The aesthetic rewards are then
591 added to associative rewards, creating
592 a particularly strong impression. It is also likely
593 that sexual selection spurred the evolution of our
594 aesthetic disposition; that is, mate choice may
595 have depended to some extent on musical and
596 visual artistic abilities. Most of the advanced
597 acoustic signals in nature are courtship signals.
598 It is easy to imagine that competence in singing,
599 or in following a rhythm, has improved the odds
600 of success in a human courtship situation. The
601 theory would help explain why love is the most

602 popular theme for songs. Skill in decorating the
603 body may have served a similar purpose.

604 Although cultural functions, particularly in
605 terms of sexual display, probably contributed to
606 the evolution of aesthetic appreciation, it seems
607 unlikely that they represent the primary mover.
608 I believe the aesthetic elements of the type
609 described in this entry preceded possible social
610 benefits. Sexual selection tends to expand partic-
611 ular features, among the more famous are the
612 peacock's feathers, but generally the feature to
613 be expanded was present before sexual selection
614 started using it. In the absence of the aesthetic
615 elements, the other functions of art would proba-
616 bly not have emerged.

617 **For the Service of Life Quality**

618 The life of dogs depends on a keen sense of smell.
619 Dogs are unlikely to insist on going to a concert,
620 or to an art exhibition, but they certainly would
621 appreciate a "gallery" where they can sniff inter-
622 esting odors. Compared to dogs, we are expected
623 to derive more pleasure from auditory and visual
624 signals, and less from olfactory signals, simply
625 because the auditory and visual signals are more
626 important for human survival. Present music and
627 art are designed to hit pleasure circuitries in the

brain with maximum power. The artist accentu- 628
ates the elements capable of stimulating brain 629
rewards. That is, they offer exaggerated stimuli 630
akin to the way a nesting bird will prefer a plastic 631
egg if it is bigger than the real egg. The role of art 632
in present society is far from being adaptive in 633
a biological sense. Then again, there is no reason 634
why it should be. It seems more rational to define 635
the purpose of life as improving life quality, 636
rather than maximizing procreation. The term 637
Darwinian Happiness offers an expansion of 638
this way of looking at quality of life. The various 639
reward mechanisms activated by aesthetics offer 640
an excellent strategy for happiness. Artists, who 641
are capable of finding novel ways of hitting the 642
relevant rewards, should be valued. 643 Au3
